Quarterly theory - Higher timeframes To Lower timeframes.

D:
Quarterly Theory breaks down time frames into four equal parts or quarters, creating a fractal structure that allows traders to observe market behavior in a highly systematic and time-based approach. Each time frame—from the week down to 15-minute intervals—is divided into these quarters. In this theory, banks and institutions exploit these time frames to align with predictable liquidity movements, making it possible to anticipate major institutional actions based on the quarter's pattern.

Here's a breakdown of Quarterly Theory's main timeframes and how banks might interact with each:

Weekly Quarters

1. Monday (1st Quarter): This is often a setup day where institutional traders may position orders without causing dramatic shifts. Institutions analyze market conditions, identifying key liquidity areas that could be exploited later in the week.

2. Tuesday (2nd Quarter): This day often brings the first signs of liquidity seeking as banks assess the prior day's setups. Institutions frequently manipulate price movements to induce premature traders into positions, setting up liquidity traps.

3. Wednesday (3rd Quarter): Known as the "Midweek Reversal," Wednesday is when institutions often initiate larger moves. Banks may reverse or retrace prices to grab liquidity, luring traders to exit prematurely, before aligning price toward the week's trend direction.

4. Thursday (4th Quarter): This is generally a continuation phase, solidifying the trend established on Wednesday. Institutions consolidate positions, leaving subtle clues that prepare the market for a reset.

Monthly Quarters

1. Week 1 (1st Quarter): The beginning of each month sees a fresh influx of capital. Institutions may initially create a range, gathering liquidity from traders who enter impulsively. This phase can often be manipulated to trap early trend followers.

2. Week 2 (2nd Quarter): In the second week, banks start to expand on the initial range created. They build liquidity for potential large moves while still giving mixed signals to retail traders.

3. Week 3 (3rd Quarter): The third week frequently acts as a confirmation or reversal point. Banks and institutions leverage this time for substantial shifts in price action, utilizing the liquidity built up over the first two weeks.

4. Week 4 (4th Quarter): The final week of the month is where institutions often take profits and rebalance their portfolios. Prices may range as banks begin closing positions or preparing for the next month's initial setup.

Quarterly (Three-Month) Cycle

1. Month 1 (1st Quarter): Institutions may use this time to establish key zones for the quarter. They often explore high and low liquidity zones, creating a baseline for the quarter's range.

2. Month 2 (2nd Quarter): After the first month's setup, banks initiate directional movement. They lure traders into believing in certain trends only to exploit those positions with retracements or reversals.

3. Month 3 (3rd Quarter): The third month frequently sees an extension of the established trend, with institutions pushing prices toward quarterly highs or lows to close with profitable positions.

Daily Quarters (Intraday Cycles)
1. London Open (1st Quarter, around 3-4 AM EST): This period is marked by liquidity injections as banks in Europe begin trading. Initial moves often create inducements or “false” directions to trap retail traders.

2. New York Open (2nd Quarter, around 8-9 AM EST): US banks enter, usually triggering a reversal or expansion phase. Banks use this overlap to trigger breakouts and collect liquidity.

3. New York Close/Asian Session (3rd Quarter): Following New York’s session, banks begin to reduce their positions, and the market enters a range. This phase is quieter but still relevant for observing institutional bias.

4. London Pre-Market (4th Quarter): As liquidity builds for the upcoming London session, banks may induce subtle movements that act as setups for the next day's initial quarter.

15-Minute Quarters (High Precision)

The 15-minute quarters offer granular insights into institutional moves within an hour. Each quarter serves a unique purpose:

1. 1st Quarter (Initial Setup): Here, banks test liquidity zones, often inducing quick swings.

2. 2nd Quarter (Manipulation Phase): Institutions may drive prices to extremes to trap retail traders on the wrong side.

3. 3rd Quarter (Reversal or Continuation): In this phase, a strong reversal may occur as institutions align with the true trend.

4. 4th Quarter (Profit-Taking/Positioning): Institutions often take profits, leaving traces that set up the next significant move.

Summary of Bank and Institutional Behavior Across Quarters

Banks and institutions primarily use quarterly theory to exploit liquidity across different timeframes, manipulating price to fulfill their objectives at predictable times. By aligning entries around quarterly turning points, they can drive retail positions into liquidity zones, set traps, and achieve efficient price delivery. Recognizing these cyclical patterns can reveal opportunities for precise entries and exits in sync with institutional flows, allowing traders to capitalize on the very structures banks use for market dominance.

I have never released this sort of information before.
